ABSTRACT

The aim of the study is to investigate anti-inflammatory properties of polar and non-polar extracts prepared from Critonia aromatisans and Montanoa grandiflora, two common native species used in Mayan traditional ointments to treat inflammation, joint pain and rheumatism. The anti-inflammatory properties of methanol/acetonitrile and n-hexane leaf extracts were tested in vivo and in vitro. The extracts of C. aromatisans and M. grandiflora decreased in a concentration-dependent manner lipopolysaccharide (LPS)-induced nitric oxide (NO) production without affecting the cell viability. The extracts of C. aromatisans at dose of 200 mg/kg exhibited substantial anti-inflammatory activity in the carrageenan-induced paw oedema test and 12-O-Tetradecanoylphorbol-13-acetate (TPA)-induced ear oedema inhibition assay with a reduction in inflammation of up to 90 and 80%, respectively. These results validate the traditional uses by Mayan communities that endorse the use of this species to treat inflammation.

Key words: Critonia aromatisans, Montanoa grandiflora, inflammation, carrageenan, nitric oxide, macrophages

RESUMEN

El objetivo del estudio es investigar las propiedades antiinflamatorias de extractos de Critonia aromatisans y Montanoa grandiflora, dos especies nativas comunes utilizadas en ungüentos tradicionales mayas para tratar la inflamación, dolor en las articulaciones y el reumatismo. Las propiedades antiinflamatorias de extractos metanol/acetonitrilo y n-hexánicos de hojas
fueron evaluados in vitro e in vivo. Los extractos de *C. aromatisans* y *M. grandiflora* disminuyeron la producción de óxido nítrico (NO) inducida por lipopolisacárido (LPS) de manera dependiente de la concentración sin afectar la viabilidad celular. Los extractos de *C. aromatisans*, a dosis de 200 mg/kg exhiben actividad antiinflamatoria sustancial en el ensayo de edema plantar inducido por carragenina y en el ensayo de inhibición de edema de la oreja inducido por TPA con una reducción en la inflamación de 90 y 80%, respectivamente. Estos resultados validan los usos tradicionales de las comunidades mayas que avalan el uso de esta especie para el tratamiento de la inflamación.

**Palabras clave:** *Critonia aromatisans, Montanoa grandiflora*, inflamación, carragenina, óxido nítrico, macrófagos.

**INTRODUCTION**

In Yucatán, México, ancient Mayan knowledge has provided remedies for the treatment of diverse ailments, especially among rural populations. Inflammation is a response induced by pathogens, damaged tissue or autoimmune and inflammatory diseases. Physiologically, inflammation operates in a restricted environment to eradicate infected or devitalized tissue. Although usually beneficial to the host, inflammation is intrinsically destructive to the immediate surroundings (Ahmed et al., 1995). Rheumatism is a term used to describe the inflammation or degeneration of the connective tissues of the body, and this condition affects primarily the muscles, joints and tendons, among other tissues. Rheumatism can also refer to the autoimmune disease that leads to the deformity of muscles or joints (joint destruction) (Zuther, 2009). Several molecules are involved in the inflammatory response, including prostaglandins and nitric oxide (NO) (Gallin and Snyderman 1999; Koeberle and Werz 2015). NO production by activated macrophages has been shown to mediate immune functions, including antimicrobial and antitumor activities. However, excess NO production has been implicated in inflammatory processes, septic shock, asthma and autoimmune diseases such rheumatoid arthritis (Mac Micking et al., 1995; Jerzynska et al., 2014). Therefore, the inhibition of NO production has become a therapeutic target for the treatment of inflammatory diseases (Azadmehr, 2009; Wen-Jun. et al., 2015).

Inflammation affects many people worldwide, and homemade remedies prepared from single plants or mixtures of plants are used in several cultures to treat these symptoms. Two common plants used in the Yucatán Peninsula to treat inflammation and rheumatism are *Critonia aromatisans* (DC.) R.M. King & H. Rob. and *Montanoa grandiflora* DC., members of the Asteraceae family. These plants are commonly used alone, together or in different plant mixtures to prepare anti-inflammatory and anti-arthritis remedies. *C. aromatisans* (formerly *Eupatorium hemipteropodum*) is known in Mexico as “Chiople” and in Cuba as “Trébol de olor”. Mayan people traditionally apply the leaves to the painful area; for example, the leaves are applied to the forehead to treat migraines. The leaves are also used to prepare decoctions to treat oedema and can be used as a poultice or in ointments elaborated with petrolatum (Méndez-Gonzáleze et al., 2012). The production of such ointments involves pulverizing the leaves and boiling them with petrolatum. The mixture is filtered and placed in containers. Then, it is ready to
use topically on the affected area of the body. The leaves have also been used to aromatize tobacco (Roig, 1974). This species has never been chemically or biologically evaluated. Montanoa grandiflora (Eurycoma hartwegiana) is known as the “daisy tree,” and its flowers are used ornamentally. This plant possesses a resinous fragrance, and in traditional Mayan medicine, the leaves are used to treat rheumatism (alone or as a poultice) and stomach aches (Méndez-González et al., 2012). There are no reports on the biological properties of this plant. Therefore, the aim of this investigation was to evaluate the anti-inflammatory activities of the polar (methanolic/acetonitrile) and non-polar (hexanic) extracts of these two plants that are traditionally used to alleviate symptoms of inflammation.

**METHODS**

**Abbreviations**

NO (nitric oxide), CA (Critonia aromatisans), MG (Montanoa grandiflora), MeOH (methanol), acn (acetonitrile), hx (hexane), DMSO (dimethyl sulfoxide), TPA (12-O-tetradecanoylphorbol-13-acetate), DMEM (Dulbecco’s Modified Eagle Medium), MTT (3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl tetrazolium bromide), CAacn (MeOH/acn extract from C. aromatisans), CAhx (hx extract from C. aromatisans), MGacn (MeOH/acn extract from M. grandiflora), MGhx (hexanic extract from M. grandiflora).

**Plant material**

Leaves from C. aromatisans (871.2 g) and M. grandiflora (127.3 g) were collected from the botanical garden of the Traditional Medical Centre of Yaxcabá, Yucatán, México. at 1 km N of the road to “Libre Unión” town. Both species were collected in June 2010 and were identified by taxonomist professor Mendez-González. A voucher specimen of each plant was deposited at the Herbarium “Roger Orellana” of the Centro de Investigación Científica de Yucatán (CICY) under the collection numbers A. Dorantes 134 (C. aromatisans) and M. Méndez 1754 (M. grandiflora).

**Preparation of the extracts**

Powdered leaves of the plants were extracted with methanol (MeOH) at room temperature (three times) to obtain the C. aromatisans (243 g) and M. grandiflora (21 g) MeOH extracts. A portion of each methanolic extract (1 g) was dissolved in MeOH, and then acetonitrile (acn) was added (1:3). This mixture was extracted with hexane, and then, both phases were separated to obtain the non-polar hexanic (CAhx and MGhx) and polar MeOH/acn fractions (CAacn and MGacn).

**In vitro assays**

**Isolation and cell culture of peritoneal macrophages**

Macrophages were isolated from the peritoneal cavities of male ICR mice. Briefly, macrophages were harvested immediately by lavage with 10 mL of cold sterile PBS injected into the peritoneal cavity of each mouse, and the resultant exudates were immediately collected, washed two times with PBS, re-suspended and adjusted to 1x10⁶ cells/mL in DMEM containing 10% inactivated foetal bovine serum, 100 U/mL penicillin and 100 µL streptomycin (referred to as complete DMEM). Fifty-microliter
aliquots of the cell suspension (5 x 10⁴ cells/well) were cultured in 96-well plates with 200 µL of complete DMEM for 24 h at 37°C in a humidified 5% CO₂ incubator. Non-adherent cells were removed by gentle washing with DMEM, and then, freshly prepared medium containing the plant extracts was added.

**Treatment of peritoneal macrophages**

Purified peritoneal macrophages (5 x 10⁴ cells/well) were incubated with the plant extracts at different concentrations (1, 10, 100, 500 and 1000 µg/mL). A control group treated with DMEM was included. The plates were maintained at 37°C in a humidified 5% CO₂ incubator. After incubation, the supernatants were removed, and LPS (1 µg/mL) was added to the culture. The supernatants were collected after 72 h of LPS treatment for nitrite determination.

**Measurement of nitrite production**

Nitrite production, an indicator of NO synthesis, was determined by the Griess reaction (Green, 1982). Briefly, 50 µL of supernatant from each well of the 96-well plates were incubated with an equal volume of Griess reagent (1% sulphanilamide/0.1% naphthalene diamine dihydrochloride/2.5% H₃PO₄) for 10 min at room temperature to quantify the level of nitrite (Ding, 1988). The absorbance was determined at 550 nm using a microplate reader. The relationship between the absorbance and the concentration of NO was determined using dilutions of sodium nitrite in culture medium with known concentrations (0-100 µM) as standards.

% proliferation = (OD sample-OD control/OD control) x 100

**In vivo assays**

**Animals**

Male and female Balb/C mice (20-25 g) were purchased from the Animal Breeding laboratories of CIBO-IMSS (Guadalajara, Jalisco, Mexico). ICR mice (20-25 g) were provided from the Animal House of Centro de Investigaciones Regionales “Dr. Hideyo
The animals were provided a standard pellet diet and water ad libitum. Five animals were used in each group. The animals were processed according to the ethical guidelines for Mexican procedures (Norma oficial Mexicana NOM-062-ZOO, 1999).

**Preparation of test samples**

Mice were weighed and then treated per os with 200 mg/kg of extract previously dissolved in a solution of 5% Tween 80 in water. The control group received 100 µL of 5% Tween 80 in pure water and received the same experimental handling as the test groups. The anti-inflammatory drug indomethacin (10 mg/kg) was used as a positive control (Boughton-Smith, 1993).

**Carrageenan-induced hind paw oedema in Balb/c mice**

The *in vivo* anti-inflammatory activity was evaluated using the carrageenan-induced hind paw oedema model with slight modifications (Winter, 1962). Briefly, four experimental groups and two control groups (positive and negative) were formed. Five Balb/c mice were included in each group and 30 min after the oral administration (200 mg/kg) of the test sample or vehicle, a suspension of carrageenan (Sigma, St. Louis, MO, USA) at 1% (0.25 µL/paw) in sterile physiological saline solution (0.9%) was injected into the subplantar tissue of the right hind paw of each mouse. The thickness of the hind paw was measured before oral administration and 3 h after injection with carrageenan. The difference in footpad thickness was measured using a precision micrometer. The mean values of treated groups were compared with the mean values of the untreated control group (negative control), and the percentage inhibition of inflammation was calculated.

**TPA-induced mouse ear oedema**

Four experimental groups and two control groups (positive and negative) were formed, with five Balb/c mice in each group. Briefly, 2.5 µg of TPA (12-O-tetradecanoylphorbol-13-acetate) dissolved in 20 µL of acetone was applied to each side of the right ear of each mouse in the experimental groups. This thickness of the ear was measured before oral administration and 3 h after the TPA was applied. The difference in ear thickness was measured using a precision micrometer. The mean values of the treated groups were compared with the mean values of the untreated control group, and the percentage inhibition of inflammation was calculated.

**Acute oral toxicity**

Acute oral toxicity was assessed in a short-term observation period of 72 h over morbidity and mortality of the animals (OECD, 2001). The mice were treated with a single dose of 200 mg/kg of the polar and non-polar extracts of *C. aromatisans* and *M. grandiflora*. The mice were observed for 4 h after the administration of the samples, paying special attention to the changes and alterations in behaviour and appearance of the fur. The observations were continued for 1 h each day. The following indicators of toxicity were assessed and recorded: breathing, pruritus, lethargy, appearance of the fur, excessive consumption of water, changes in eyes and mucous membranes, walking alterations, position, manipulation, drowsiness, self-cleanliness, convulsions,
salivation, diarrhoea, auto mutilation, coma and death.

**GC-MS Analysis**

Preliminary analyses of the n-hexanic extracts were performed by gas chromatography/mass spectrometry with an Agilent technologies 6890N system equipped with an HP-5 MS capillary column (30 m × 25 mm x 0.25 µm). Helium was used as the carrier gas; the injection volume was one microliter, and the temperature program used was as follows: 50°C (3 min); an initial temperature of 80°C (5 min.); an increase to 215°C at 4°C/min; and a hold at 215°C for 5 min. The identification of the components was based on the comparison of their mass spectra fragmentation with those reported in the NIST05 compounds library.

**Statistical analysis**

For cell viability, experimental values are expressed as the mean ± standard deviation of at least three experiments performed in triplicate. The data were analysed using one-way ANOVA with Dunnett’s multiple comparisons test. For *in vivo* pharmacological evaluations, experiments were performed with five animals per group. For *in vivo* and *in vitro* tests, experimental values are expressed as the mean ± standard error of the mean (S.E.M.). Statistical analysis was performed by one-way analysis of variance (ANOVA) with the Bonferroni *post hoc* test using PRISMA (GraphPad Software, Inc., San Diego, CA, version 5.01). In both cases, p ≤ 0.05 was used as the criterion for statistical significance (sample vs. control).

**RESULTS**

*In vitro effects of C. aromatisans and M. grandiflora on NO production by mouse peritoneal macrophages*

In the present study, it was observed that the extracts of *C. aromatisans* and *M. grandiflora* inhibited NO production in a concentration-dependent manner (fig. 1). The highest activity was found for the non-polar extract of *C. aromatisans* (CAhx). This extract almost completely inhibited NO production (97.58% inhibition) by peritoneal macrophages at the concentrations of 500 and 1000 µg/mL. No effects on the viability of peritoneal macrophages exposed to different concentrations of extracts were observed, indicating the potential specificity of the extracts for NO production by macrophages.

**Cell Viability**

Cell viability was evaluated using the mitochondrial-dependent reduction of 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl tetrazolium bromide (MTT) to purple formazan. It was showed that the treatments with 1, 10, 100, 500 and 1000 µg/mL with the extracts did not alter the viability of mice peritoneal macrophages.

*In vivo anti-inflammatory effects*

In the carrageenan-induced hind paw oedema model (table 1), the non-polar (CAhx) and polar extracts (CAacn) of *C. aromatisans* at the dose of 200 mg/kg resulted in the maximum inhibition (92 and 96%, respectively).
Fig. 1. Effect of CAacn, CAhx (Fig. 1A) and MAacn, MGhx (Fig. 1B) on NO production after 72 h of activated mouse peritoneal macrophages. Control (-) represent non activated peritoneal macrophages. LPS represents activated peritoneal macrophages with LPS without extracts treatments. NO production by LPS activated peritoneal macrophages was significantly (*p < 0.05) inhibited when different concentration (1, 10, 100, 500, 1000 µg/mL) of extracts were added. Data represent mean ± S.D. values from the three independent experiments.

Villa-De la Torre, F. et al.: Anti-inflammatory activity of Critonia aromatisans and Montanoa grandiflora leaves extracts.

Effectively, paw oedema at 3 h after carrageenan injection. Similar results were obtained for the TPA-Induced mouse ear oedema model (table 2), in which both extracts of *C. aromatisans* showed anti-inflammatory effects of up to 80% at the same dose. These effects were similar in both cases to the effects of the anti-inflammatory drug indomethacin. In contrast, the extracts obtained from *M. grandiflora* showed lower values of reduction of inflammation in the carrageenan-induced hind paw oedema model (table 2). In the TPA-induced mouse ear oedema model, no anti-inflammatory effect was observed for the non-polar or polar extract of *M. grandiflora* at the dose of 200 mg/kg.

**Acute toxicity**

In the acute toxicity test, the four groups treated with the extracts of *C. aromatisans* and *M. grandiflora* showed no signs of adverse effects, abnormal behaviour, toxicity or lethality at the dose of 200 mg/kg 72 h after administration.

**GC-MS**

Gas chromatography-mass spectrometry analysis of the non-polar extracts of *C. aromatisans* and *M. grandiflora* showed that they were primarily composed of fatty acids and terpenoids (Figure S1-S22); *C. aromatisans* registered four major compounds at retention times (RT) of 7.51, 10.01, 10.94 and 20.57 min (Figure S1 in supplementary material) which included 2H-1-benzo-pyran-2-one, isoloongifolen-5-one, methyl palmitate and Lup-20 (29)-en-3-ol, acetate, respectively (figure S2, S5, S7, S11). Other minor components were identified as ledol, 2-pentadecanone, stigmasterol, lupeol and β-sitosterol. *M. grandiflora* contained six main compounds at RT of 8.64, 17.17, 20.09, 20.49, 21.44 and 21.59 min (figures S14, S17-S19, S21,S22 in supplementary material) with mass fragmentation pattern similar to caryophyllene oxide, hentriacontane, 12-Oleane-3-yl acetate, Lup-20 (29)-en-3-ol, acetate. Compounds with retention times at 21.44 and 21.58 min were not found in the NIST library (figures S21 and S22).

**DISCUSSION**

Different models were used to evaluate the anti-inflammatory effects of *C. aromatisans* and *M. grandiflora*. The *in vitro* experiments were performed using the nitric oxide test. It is well known that during an inflammatory process, after signalling events, macrophages induce the expression of pro-inflammatory enzymes such as inducible nitric oxide synthase (iNOS). This enzyme is regulated by the secretion of pro-inflammatory cytokines and produces NO from L-arginine. Large amounts of NO can cause severe collateral damage in the tissue because NO can form peroxynitrite (ONOO•), a cytotoxic molecule related to inflammatory pathologies. For this reason, the regulation of the production of NO is an important target for inflammatory diseases (Guzik *et al.*, 2003).

The *in vivo* anti-inflammatory effects of the extracts were measured using the carrageenan-induced hind paw oedema and TPA-induced ear oedema models. These two models are well-known indicators of acute inflammation, and both evaluations can be performed at the same time because they use the same animals and the same treatment doses. In addition, both models allow the rapid evaluation of the effect of an extract or compound with potential anti-inflammatory...
properties. When the polysaccharide carrageenan is injected into the hind paw, it produces oedema mediated by white blood cells (neutrophils, monocytes and lymphocytes), major inflammatory mediators such as NO, prostaglandin E2 (PGE2) and the cytokines TNF-α and IL-6 (Kim, et al., 2012). TPA is a topical oedematogenic agent and causes skin irritation and tumour promotion, because it stimulates PKC, which plays a critical role in signal transduction pathways and regulates cell growth and differentiation (Nishizuka, 1992). TPA affects the membrane, resulting in altered cell adhesion and the induction of arachidonic acid metabolism, specifically causing the release of prostaglandins, which are responsible for oedema (Weinstein et al., 1979). The results obtained in the present work, suggest that the different groups of anti-inflammatory metabolites of C. aromatisans are distributed between both polarities. Also, these results could indicate that the possible anti-inflammatory mechanism of MGhx (which showed an anti-inflammatory effect only in the carrageenan model) does not involve the PKC pathway. Further in vitro experiments can elucidate the specific anti-inflammatory mechanism of MGhx. A literature search for C. aromatisans did not found any previous chemical study. A previous study of M. grandiflora revealed the presence of limonene, citronella, camphene, pinene and phellandrene in essential oils prepared from the inflorescences, stems and leaves (Pérez-Amador et al., 2006). The compound 6β-hydroxy-germacradien-8,12-oxide was obtained from the chloroform extract of M. grandiflora (Quijano et al., 1984). Different species of the Asteraceae family, including species of the genus Eupatorium, contain terpenoids, such as stigmasterol and taraxeryl acetate. Stigmasterol is able to reduce pro-inflammatory mediators such as NO and PGE2 in RAW 264.7 murine macrophages in vitro (Pandith et al., 2013). Taraxeryl acetate reduces inflammation in in vivo models such as hind paw oedema induced by carrageenan and mouse ear oedema induced by TPA (Pérez-García et al., 2005). In this preliminary evaluation of the non-polar extract of C. aromatisans, stigmasterol was found, but taraxeryl acetate was not. Stigmasterol has a known anti-inflammatory effect, and other components of the non-polar extract may contribute to this effect in a synergistic manner. In the in vitro evaluation, it was observed that the extracts inhibited NO production in a concentration-dependent manner, and this activity might be responsible for their in vivo anti-inflammatory properties. However, considering that there exist different mediators that can be inhibited to produce the anti-inflammatory effect, further studies are necessary. The presence of terpenoids and fatty acids in the non-polar extracts could validate the use of this species in traditional medicine and the use of petrolatum to prepare the ointments. Because of its non-polar composition, petrolatum would retain the non-polar compounds and essential oils from the leaves, and then it can be administered topically. Due to these interesting results, the isolation and characterisation of the bioactive compounds in each plant are recommended. Based on the present work, it can be concluded that the non-polar and polar extracts of C. aromatisans and the non-polar extract of M. grandiflora possess in vitro and in vivo anti-inflammatory activities, and both species seem to be useful to treat inflammatory symptoms.
CONCLUSION

The results obtained in the present study show fundamentals to validate the traditional uses by Mayan communities that endorse the use of this species to treat inflammation. Additionally, *C. aromatisans* has shown a stronger *in vivo* and *in vitro* activity, and one of the possible mechanisms of the anti-inflammatory response is the inhibition of the NO production.

ACKNOWLEDGEMENTS

The authors thank to CONACyT [Grant number 201275] for providing us the funding support to perform this study. We would also like to thank doctor Ivan Delgado from the University of Guadalajara, Jalisco, México, for the assistance with the animal management and care. We would also like to acknowledge Alfredo Dorantes for his support during sample collection and processing of the plant material.
